The genus *Eoferreola* Arnold, 1935 in the Palaearctis with description of a new species (Hymenoptera: Pompilidae)*

*pdf-file, made by the final draft, the original paper may include some minor changes.

Sex symbols : (£) = femelle; (\$) = mâle

Abstract

Eight *Eoferreola* species of the Mediterranean area and central Asia are revised: ***Eoferreola anatolica*** Priesner, 1973 - ***Eoferreola cyrenaica*** (Guiglia, 1941): (*Paraferreola facilis* Priesner, 1966 new synonym; *Paraferreola anomala* f. *croceicornis* Priesner; new synonym) - ***Eoferreola distincta*** (Smith, 1855): (*Ferreola distincta* Smith, 1855: 169 new combination; *Ferreola syraensis* Radoszkowski, 1889 new synonym; *Eoferreola schmidti* Priesner, 1973; new synonym, *Eoferreola manticata* f. *cinerata* Priesner, 1973 new synonym; *Salius grandis* Radoszkowski 1887, new synonym) - ***Eoferreola erythraea*** (Pallas, 1773): (*Ferreola sirdariensis* Radoszkowski, 1889: new synonym) - ***Eoferreola manticata*** (Pallas 1771): *Salius Hellmanni* Eversmann, 1849 new synonym. - ***Eoferreola mixta*** (Tournier, 1895) - ***Eoferreola neftae*** Schmid-Egger new species from north Africa - ***Eoferreola rhombica*** (Christ 1791). Most of the species are represented by different color forms. A key to species identification is presented. The following species do not belong to *Eoferreola*: *Paraferreola simplex* Haupt, 1962 = ***Apareia simplex*** (Haupt, 1962), new synonym; *Ferreola pici* Tournier, 1895 = ***Ferreola algira*** Lepeletier 1845, new synonym.

Acht *Eoferreola*-Arten aus dem Mittelmeerraum und Zentralasien werden revidiert: ***Eoferreola anatolica*** Priesner, 1973 - ***Eoferreola cyrenaica*** (Guiglia, 1941): (*Paraferreola facilis* Priesner, 1966, neues Synonym; *Paraferreola anomala* f. *croceicornis* Priesner; neues Synonym) - ***Eoferreola distincta*** (Smith, 1855): (*Ferreola distincta* Smith, 1855: 169 neue Kombination; *Ferreola syraensis* Radoszkowski, 1889 neues Synonym; *Eoferreola schmidti* Priesner, 1973; neues Synonym, *Eoferreola manticata* f. *cinerata* Priesner, 1973 neues Synonym; *Salius grandis* Radoszkowski 1887, neues Synonym) - ***Eoferreola erythraea*** (Pallas, 1773): (*Ferreola sirdariensis* Radoszkowski, 1889: neues Synonym) - ***Eoferreola manticata*** (Pallas 1771): *Salius Hellmanni* Eversmann, 1849 neues Synonym. - ***Eoferreola mixta*** (Tournier, 1895) - ***Eoferreola neftae*** Schmid-Egger, neue Art aus Nordafrika - ***Eoferreola rhombica*** (Christ 1791). Die meisten Arten treten in mehreren Farbformen auf. Ein Schlüssel für alle Taxa wurde erstellt. Die folgenden Arten gehören nicht zu *Eoferreola*: *Paraferreola simplex* Haupt, 1962 = ***Apareia simplex*** (Haupt, 1962), neues Synonym; *Ferreola pici* Tournier, 1895 = ***Ferreola algira*** Lepeletier 1845, neues Synonym.

Introduction

The genus name *Eoferreola* appeared for the first time in the year 1935 when Arnold created it as subgenus of *Paraferreola* Sustera, 1913 for *Anoplus soleanus* Cameron, 1905 from South Africa. Arnold based his subspecies on the form of the propodeum which is rounded and not with lateral edges as in other species of the genus. Arnold placed *Anoplus melanostoma* Cameron and *spilopus* Cameron in

Wahis, R. & C. Schmid-Egger (2002): The genus *Eoferreola* Arnold, 1935 in the Palaearctis with description of a new species (Hymenoptera: Pompilidae). Notes faunistiques de Gembloux 46: 39-73.

Paraferreola s. str., 1905 which represent two sexes of the same species (*A. spilopus* is a new synonym of *A. melanostoma*).

The name *Paraferreola* was proposed by Sustera in 1913 to distinguish *Ferreola* Smith and auct. which was created by Lepeletier in 1845 (type species: *Ferreola algira* Lepeletier). *Paraferreola* united at this time a series of species described by Pallas, Radoszkowski, Tournier, Eversmann, Christ and Smith (cf. Haupt, 1927) in different families and genera as *Sphex*, *Pompilus*, *Ferreola* and *Salius*. Sustera designated *Sphex ursus* of Fabricius, 1793 as type. Schulz discovered unfortunately after examining the type in 1912 that it is a male of a Mutillidae and underscored that *Paraferreola* is not suited as genus name in Pompilidae. Haupt (1927) emphasized this fact but nevertheless kept the name and designated as type species *Paraferreola rhombica* Christ.

Because of this, Pate (1946) created the subgenus *Tea* to regroup the *Paraferreola* of authors, nec. Sustera, with the type species *Sphex rhombica* Christ, 1791. Wahis (1970) discussed the case and concluded that *Eoferreola* must replace *Tea*, because it was the older name (has priority).

The mediterranean species of *Eoferreola* were never revised nor really examined until now. Most former authors (Haupt 1927, Priesner 1966, Wolf 1972) did not recognize suited characters for species recognition. So the male sternal depressions of *E. distincta* and other species was never mentioned in the literature before. The present revision proposes characters for species distinction, recognizes and characterizes species and clarifies the taxonomic situation of all described *Eoferreola* taxa in the treated area.

Sources of material

Species from the following institutions and private collections were examined (abbreviations use are given):

Institutions:

BERLIN: Museum für Naturkunde der Humboldt-Universität, Berlin, Germany (F. Koch).

BRUXELLES : Institut royal des Sciences naturelles de Belgique, Bruxelles, Belgique.

GEMBLOUX : Faculté universitaire des Sciences agronomiques, Gembloux, Belgique (C. Gaspar).

GENOVA: Museo Civico di Storia Naturale "Giacomo Doria", Genova, Italy (V. Rainieri).

HALLE: Zoologisch Institut, Halle/Saale, Germany (M. Dorn).

LAUSANNE: Musée Zoologique, Lausanne, Switzerland (M.Sartori).

LONDON: Natural History Museum, London, U.K. (before M.C.Day, at present Miss S. Lewis)

LINZ: Oberösterreichisches Landesmuseum, Linz, Austria (F. Gugenleitner).

MONS: Université de Mons-Hainaut, Mons, Belgique. (P.Rasmont)

MONTPELLIER: Institut national de Recherche agronomique, France (C. Cocquempot).

MÜNCHEN: Zoologische Staatssammlung, München, Germany.

PARIS: Muséum national d'Histoire naturelle, Paris, France (Mme J. Weulersse) (coll. H. Barbier, Cleu, DeGaulle, Benoit, Bernard, Bitsch, Ferton, Giraud, Hamon, Marion, Pérez, Roth, Sichel, Vachal, Vauloger).

STUTTGART: Staatliches Museum für Naturkunde, Stuttgart, Germany (T.Osten).

TORINO: Museo ed Istituto di Zoologia Sistematica della Universita di Torino, Torino, Italy (A.Rolando).

TROYES: Musée d'Histoire naturelle de la ville de Troyes, France (coll. Maldes).

VERSAILLES : Institut national de Recherche agronomique, Versailles, France.

WIEN: Naturhistorisches Museum, Wien, Austria (M. Fischer).

Private collections:

Wahis, R. & C. Schmid-Egger (2002): The genus *Eoferreola* Arnold, 1935 in the Palaearctis with description of a new species (Hymenoptera: Pompilidae). Notes faunistiques de Gembloux 46: 39-73.

Adamski: A. Adamski, Chateaudun, France.
Arens: W. Arens, Bad Hersfeld, Germany.
Delmas: R. Delmas, Montpellier, France.
Hartmann: P. Hartmann, Bayreuth, Germany.
Hauser: M. Hauser, University of Illinois, Urbana, U.S.A.
Fonfria: R. Fonfria, Eygalières, France.
Gros: E. Gros, Chierry, France.
Lefeber: V. Lefeber, Maastricht, Netherlands.
Merz: B. Merz, Genève, Switzerland.
Mochi: A. Mochi, Roma, Italy.
Niehuis: O. Niehuis, Marburg, Germany.
Noblecourt: T. Nobelcourt, Antugnac, France.
Pedrero: J.J.F. Pedrero, Salamanca, Spain.
Ponel: P. Ponel, Marseille, France.

Wahis: R. Wahis, in Faculté des Sciences agronomiques, Gembloux, Belgique.
Wiering: J.E. Wiering, Bergen, Netherlands
Windschnurer: N. Windschnurer, Karlsruhe, Germany.
Wolf: H. Wolf, Plettenberg, Germany.

Key to species of *Eoferreola*

OOL = distance between lateral ocellus and eye, POL = distance between lateral ocellus

Males

1. Sternites III-IV (often also V) with large longitudinal depressions. Depressions laterally with bulge or edge (fig. xx).
- Sternites III-V flat, lacking depressions.
2.
2. Depressions on sternites III-IV laterally rounded or with rectangular edge (fig. xx). Flagellomeres all black. 13-18 mm. Southern Italy, Greece and Syria to central Asia.
Tibia III and propodeum all black. Wings darkened.
distincta (Smith)
- Depressions on sternite IV (or on sternite III-V) laterally with narrow triangular projection (fig. xx). Flagellomeres reddish. 6-13 mm. Israel to Morocco.
3.
3. Tibia II often and III apically with yellow spot. Pronotum with lateral whitish yellow band. Wings hyaline. Flagellomeres orange reddish. 6-8 mm. Israel to Morocco, Mali.
cyrenaica (Guiglia)

Wahis, R. & C. Schmid-Egger (2002): The genus *Eoferreola* Arnold, 1935 in the Palaearctis with description of a new species (Hymenoptera: Pompilidae). Notes faunistiques de Gembloux 46: 39-73.

- Tibia and pronotum black. Wings brownish darkened. Flagellomeres darker as in *cyrenaica*. 11-13 mm. Morocco to Egypt.

***neftae* Schmid-Egger new species**

- 4. Wings hyaline. Setae on head and propodeum whitish silvery. Sternite VIII narrow. Small species, 6-11 mm. Western and central Palaearctis.

***manticata* (Pallas)**

- Wings at least at apex darkened, sometimes with metallic reflexions, opaque. Setae on propodeum and head dark or pale, but not silvery white. Sternite VIII larger. Large species, 9-19 mm.

5.

- 5. Distribution: Morocco to Algeria. Wings regular brownish darkened. 13-19 mm.

***mixta* (Tournier)**

- Distribution: Southern Europe to Israel and central Asia. Wings different. 9-19 mm.

6.

- 6. Setae on propodeum dark brown or black. Wings regular brownish darkened, sometimes with darker zone along outer edge. Pubescence on frons dark. 11-13 mm. Southern Europe to central Asia, Israel.

***anatolica* Priesner**

- Setae on propodeum light brown or pale. Wings with small darkened zone along outer edge. Remaining surface of wings grayish, pale. Pubescence on frons different.

7.

- 7. Pubescence on frons dark brown. Tergite II always with red band. 9-11 mm. Europe.

***rhombica* (Christ)**

- Pubescence on frons dark pale. Tergite II black or with red band. 11-13 mm. Turkey to central Asia.

***erythraea* (Pallas)**

Females

The female of *E. neftae* Schmid-Egger new species is unknown.

- 1. Tergite II (sometimes also tergite I) with red band or two lateral red spots. Propodeum red.
2.
- Tergites black. Propodeum black or red.
3.
- 2. Pronotum black. Europe.
***rhombica* (Christ)**

Wahis, R. & C. Schmid-Egger (2002): The genus *Eoferreola* Arnold, 1935 in the Palaearctis with description of a new species (Hymenoptera: Pompilidae). Notes faunistiques de Gembloux 46: 39-73.

- Pronotum red. Turkey to central Asia.
erythraea (Pallas)
- 3. Apical margin of mesosternum (epiphyse) with long triangular elongation (visible between coxae II, fig. xx). 16-26 mm. Algeria, Italy, Greece and Syria to central Asia.
Vertex behind eye short, half as long as flagellomere X. Flagellomere I as long as POL + OOL (fig. xx). Propodeum red in European and Turkish specimens.
distincta (Smith)
- Apical margin of mesosternum rounded or with shorter elongation (fig. xx).
4.
- 4. Frons and entire surface of thorax red. Vertex behind eye half as long as flagellomere X. 12-15 mm. Tunisia to Morocco.
Flagellomere I 3,3x as long as apical width, 1,3x as long as flagellomere II.
manticata f. tournieri (Tournier)
- At least propodeum or mesonotum and scutellum black. Vertex variable.
5.
- 5. Head, pronotum, mesonotum and scutellum light red (or with red marks), propodeum black.
Flagellomere I as long as POL + OOL. 12 mm. North Africa, Israel, Mali.
Vertex behind eyes short, as long as diameter of anterior ocellus.
cyrenaica (Guiglia)
- Different color pattern. Mesonotum and scutellum black, head and pronotum variable. If smaller than 15 mm, flagellomere I shorter.
At *E. manticata*, flagellomere I is appr. 3-3,8x as long as apical width and 1,3x as long as flagellomere II (fig. xx).
6.
- 6. Pronotum and propodeum red.
7.
- Pronotum black, propodeum red or black.
8.
- 7. 15-20 mm. Vertex behind eye as long as flagellomere X. Tunisia to Morocco.
mixta (Tournier)
- 7-15 mm. Vertex behind eye short, half as long as Flagellomere X. Eastern and south-eastern Europa, Turkey, Central Asia.
manticata f. manticata (Pallas)
- 8. Whole body black. Korsica, Greece, eastern and southern Mediterranean area to Central Asia.
manticata f. batrachiorum (D. Torre)

Wahis, R. & C. Schmid-Egger (2002): The genus *Eoferreola* Arnold, 1935 in the Palaearctis with description of a new species (Hymenoptera: Pompilidae). Notes faunistiques de Gembloux 46: 39-73.

- Propodeum red.

9.

9. Large species, 15-20 mm. Vertex behind eye as long as flagellomere X. Southern Europe to central Asia, Israel.

anatolica Priesner

- Smaller species, 7-15 mm. Vertex behind eye short, half as long as flagellomere X. Southern Europe to Turkey and Azerbaydzahn.

manticata f. lichtensteini (Tournier)

Eoferreola Arnold

Eoferreola Arnold 1935: 442

Paraferreola Sustera, 1913: 181, 200

Tea Pate 1946: 109

Eoferreola anatolica Priesner, 1973

Tea caucasica (Radoszkowski); Priesner, 1967: 56 £ Turkey: Mut, Pamukkale (syn. Priesner, 1973).

Eoferreola anatolica Priesner, 1973: 109-110 £ Turkey (holotype £, coll. Priesner; Wien) examined.

Eoferreola syraensis (Radoszkowski); Wolf, 1998: 341 £ \$ Kazakstan (incorrect identification) examined.

Diagnosis and discussion: The female of *E. anatolica* has a red propodeum and black tergites, whereas the morphologically similar *rhombica* and *erythraea* have tergites touched by red. *E. anatolica* is similar in color pattern to *manticata* f. *lichtensteinii*. *E. manticata* has narrow temples (half as long as length of flagellomere X), whereas the temples of *anatolica* are larger (as long as length of flagellomere X). The male of *anatolica* is similar to these of *rhombica* and *erythraea*. It is only recognizable by its darker wings and black propodeal setae. In most cases *rhombica* is smaller than *anatolica*, but the distinction of all three species in south-east Europe and Turkey remains problematic. The similar *erythraea* has always pale propodeal setae and pale pubescence on the frons.

It is possible that *anatolica* is only a color form of *rhombica*. Some males from southern France have typical "anatolica" characters, but large females with black tergites have never been found in this area. But we treat *anatolica* as a valid species for the moment (see discussion at *rhombica*).

Priesner (1966: 146) mentioned a dark colored and 12 mm long male from Israel which he suspects to be the true male of *E. anomala*. This male was not found among the specimens from Tel Aviv; but the collection includes another completely dark colored *anatolica* male from Israel which measures also 12 mm. This male was identified as *grandis* by Priesner. Probably the mentioned "*E. anomala*" male sensu Priesner belongs also to *anatolica*.

Female: Length 17-20 mm. Black, propodeum red. Wings brownish clouded, lateral margin of wings darker than its surface. Temples and flagellomeres similar to *rhombica*. Flagellomere I as long as OOL + 0,5 POL. Temples long, as long as length of flagellomere X. Apical border of metasternum rounded. On the specimen from Madrid sides of propodeum are partly black and inner orbits and upper margin of eye are reddish.

Male: Length 11-15 mm. Black, tergite II with large red band (in basal two-thirds II. Erect setae of head brown, setae of propodeum nearly black with brownish gleam. Wings dark brownish clouded, lateral margin darker than its surface. Sternites flat, without depressions. A male from Israel has complete black abdomen with very weak red spots on tergite.

Distribution: Southern Europe to central Asia, Israel.

Paraferreola anomala; Priesner, 1955: 185 £ Egypt: Ikingi (holotype £; Alfieri, ?Caire).

Paraferreola anomala Haupt; Priesner, 1966: 145-146 £\$ (£ paratype and \$ allotype examined).

Paraferreola anomala f. *croceicornis* Priesner, 1966: 146: Abu Kebir; Djermak (2 \$ types; Bitinski-Salz) examined, **new synonym**.

Diagnosis and discussion: The female is characterized by its long flagellomere I (as long as OOL + POL, fig. xx), its short temples and its unique color pattern. The upper part of the head and thorax to the postscutellum are red. The unknown female of *neftae* might be similar to *cyrenaica* because of the morphological similarity of the males.

The male of *cyrenaica* is unique in the mediterranean area characterized by its sternal depressions, its pale marks on the pronotum and on the tibia III; and its light red flagellomeres. Both other species with sternal depressions have a dark pronotum and tibia, the flagellomeres are black in *distincta* and dark reddish in *neftae*.

Female: Length 11-16 mm. Red are: Inner margin of eyes, upper part of head (area around ocelli dark), pronotum, mesonotum, scutellum and central spot on postscutellum. Extention of color variable. Color varies between dark red and light orange red. Tergites I-III might have narrow and indistinct red bands. Wings dark brown with metallic reflections. Flagellomere I as long as OOL + POL, somewhat shorter in large specimens. Temples narrow, as long as twice midocellus diameter. Apical border of metasternum rounded.

Male: Length 8-11 mm. Flagellomeres light reddish. Pronotum with apical pale yellow band, shortly interrupted in the middle, not reaching lateral pronotal lobes. Tergite II reddish (sometimes dark reddish), tergite III black or dark reddish, tergite VII pale yellow. Apical third of tibia II sometimes and tibia III always pale yellow touched. Wings something darkened. Sternite III-V with medial triangular depression in apical half (depression on sternite IV as long as visible part of sternite). Depression IV laterally with triangular projection, as tall as midocellus diameter. Depression on remaining sternites without or with small projections.

Eoferreola distincta (Smith, 1855) new combination

Ferreola distincta Smith, 1855: 169 **new combination** £ Albania (£ holotype n° 19.481; London) examined. **Remark:** The replacement name *albanorum* proposed by Dalla Torre was not used because the different taxa included by the author as homonym belong to different genera (CIN, 4ème édition 1999, article 59.3). The name *distincta* Smith was never used since his creation, but does not agree with the condition of the International Code (CIN 23.g.1.1 et 23.g.1.2) and has to be used instead of the name *syraensis* from Radoszkowski.

Ferreola syraensis Radoszkowski, 1889: 474 £ Syria (£ holotype; Berlin, examined. **New synonym**).

Pompilus syraensis; Dalla Torre,1897: 326 (catalogue, new combination).

Eoferreola schmidtii Priesner, 1973: 109-110 £ Turkey (£ holotype; Wien) examined, **new synonym**.

Eoferreola manticata f. *cinerata* Priesner, 1973: 109-110 £ Turkey (£ holotype; Wien) examined, **new synonym**.

Eoferreola syraensis (Radozskowski); Wahis 1998: 154 \$ Turkey.

Diagnosis and discussion: *E. distincta* is characterized by the triangular prolonged apical margin of the mesosternum ("epiphyse", visible between coxae II). This character is unique within the treated species of *Eoferreola*. The female is also characterized by the prolonged flagellomere I which is as long as the distance between the eye and the opposite lateral ocellus (= POL+OOL). It shares the prolonged flagellomere with *cyrenaica*, whereas it is shorter in all other species treated here. The male of *distincta* has depressions on sternites III-IV which are laterally rounded or with a rectangular edge (fig. xx). *E.*

cyrenaica and *E. neftae* from north Africa and Israel also have depressions on the sternites, but these are laterally bounded by a prominent triangular edge. *E. distincta* is a large species (females up to 26 mm) which occur in a red colored and in a black form (see below).

Females: Length 16-26 mm. Pronotum red or black, remaining body black. Wings darkly clouded, with narrow apical margin darker than remaining wing surface. Flagellomere I as long as united OOL + POL. Temples narrow, as long as threefold diameter of midocellus. Apical margin of mesosternum prolonged.

Variation: The typical form has an orange-red propodeum and dark clouded wings. It occurs in south east Europe, Syria and Algeria (*syraensis* Radoszkowski type, sensu Haupt & Priesner). In Turkey occurs a form with a paler pubescence in lower face and pronotum (*cinerata* Priesner type). A red colored specimen with a silver pubescence on pronotum and dark clouded wings had been described as *schmidti* Priesner. Females from central Asia, Rhodos (Greece) and the eastern mediterranean area have a completely black body, dark pubescence and very dark clouded wings: *Sphex melanidus* Pallas (nomen ineditum) type, *grandis* Rad. sensu Haupt et Wolf. A female from Iran has also a completely black body, but a pale pubescence on body.

Male: Length 13-18 mm. Black, tergite II has a large basal band (as wide as 3/4 of tergal length). The band can be reduced to lateral spots, or tergite II is completely black. Head and parts of thorax covered with a brownish pubescence. Long setae on head and mesonotum pale brownish, darker brownish on propodeal dorsum.

Variation: Specimens with red colored tergite II occur in Greece and Turkey. Males from eastern Turkey have a darker pubescence and two red spots on tergite II. A form, probably also from Turkey (?Tauria) has silvery pubescence on the face, the pronotum and the propodeum. The tergite II has a dark red band on the basal half, the wings are hyaline without a dark margin (*muricatus* Pallas, *grandis* Rad. sensu Haupt). The taxon *syraensis* Rad. (dt. Haupt.) from Turkey also has a silvery pubescence, the band on tergite II is very dark red and the wings are dark clouded. Completely black colored males with dark pubescence and dark clouded wings occur in Syria and Central Asia (*grandis* Rad. sensu Wolf.).

Geographic Distribution: Greece, Turkey to Iran and Central Asia, Algeria and eastern Mediterranean area. Algeria is represented by a single old record. It is far from the main distribution and seems doubtful.

Paraferreola erythraea (Pallas); Schmiedeknecht, 1930: 624 £ \$

Paraferreola erythraea (Pallas); Haupt, 1962: 68 £ (key; Transcaspia, Iran; occurrence in Europe
doubtful)

Paraferreola caucasica (Radoszkowski); Haupt, 1962: 67 £ (key; Armenia to Transcaspia, Syr-Darja).

Diagnosis and discussion: The female of *erythraea* is characterized by its color pattern. Head, pronotum, propodeum and tergite II are rich light red in color. Otherwise the species is morphologically similar to *rhombica*. The male of *erythraea* has a silver pubescence on the head and the propodeum, whereas the similar *rhombica* and *anatolica* males have a distinctly darker body pubescence. The males of *erythraea* from Central Asia have a red colored tergite II. Females of *erythraea* have only been found in Central Asia. We also examined some males with distinct silver propodeal pubescence from Turkey which – in our opinion – belong to *erythraea*. These males have a dark red or completely black tergite II. In the same region also occur *rhombica* males which pose the question of how to distinguish males of both taxa in the eastern Mediterranean because *rhombica* males of southern origin show a tendency to paler body pubescence. It is possible that *erythraea* is only an extensive red colored form of *rhombica* from western and central Asia.

For the moment we will treat both taxa as valid species, as defined above. The problem needs further research, especially females from Turkey should be examined. The state of *anatolica* should also be examined in this context. The females and males are morphologically identical to *rhombica* and *erythraea*. The differences in color pattern in the females and the color of propodeal setae in the males might also reflect geographic variation.

Female: Length 10-18 mm. Head touched with red: Clypeus, inner orbits of eyes, vertex, area between scapus and clypeus. Flagellum reddish at underside. Pronotum completely red, lateral and hind margin sometimes dark. Propodeum red, sometimes also upper metapleural area. Tergite I and II with large lateral

Wahis, R. & C. Schmid-Egger (2002): The genus *Eoferreola* Arnold, 1935 in the Palaearctis with description of a new species (Hymenoptera: Pompilidae). Notes faunistiques de Gembloux 46: 39-73.

spots, sometimes connected. Base of tergite I and apical margin of tergite I and II black. Temples as long as 0,7-1 length of flagellomere X. Flagellomere I as long as OOL + 0,5 POL.

Variation: The females differ in size. The red color might be less extensive on the head and the upper metapleural area. Also length of temples is variable.

Male: Length 12mm. Colored like *E. rhombica*, pronotum and propodeum covered with a fine silvery pubescence. Long setae on frons are dark. Males from Turkey have dark tergites.

Geographic Distribution: Central Asia and Turkey. Records from Syria and Romania are doubtful. Syria was a misinterpretation of the type locality of *sirdariensis*, Sir-Daria, in Kazachstan ("Syrien, Darien", interpreted by Haupt).

Ferreola pici Tournier placed by Haupt 1927 as a synonym of *manticata* - a position which other authors followed – is a real *Ferreola* (de Beaumont 1970: 258). Wahis examined and designated a female in the Paris collection which was originally labelled by Tournier as lectotypus. It belongs to *Ferreola algira* Lepeletier, 1845.

The name *iberoturanica* Wolf (1970) which was also used for a black form of *manticata* was probably incorrectly referred to *Eoferreola* by the author. He used it for *Paraferreola progressiva* Haupt (nomen nudum) which belongs to the genus *Apareia* Haupt (com. n.). We could not verify the identity of the taxon because we could not see the type: *Paraferreola progressiva* Haupt, in Nadig & Nadig, 1935: 12 (nomen nudum) £ \$ Morocco: Ifrane, Casabla nca (holotype £; Zurich) examined. = *Apareia simplex* Haupt, 1962 - *Tea manticata iberoturanica* Wolf i.l.; Wolf, 1968: 234 (nomen nudum) £ Nord-Afghanistan. Distribution: S. Spain, Morocco, Turkmenistan. - *Tea manticata iberoturanica* Wolf, 1970: 399, 412 £ \$ Morocco: Rabat; Afghanistan (holotype £, coll. Wolf) not examined; put in synonymy with *Paraferreola progressiva* Haupt i.l. which belongs to the genus *Apareia* (= *Psammoderes*).

“*E. anomala*” from Israel is a black form of *E. manticata*, first described as *Pompilus niger* (= *Ferreola nigra*) by Radoszkowski. The females and males of „*anomala*“ in the type series from Tel Aviv show the typical characters of *manticata*. Priesner (1966) mentioned a black colored male in the coll. Tel Aviv which he suspected to be the male of *E. anomala*. This specimen is probably a black colored *E. anatolica* (see above). *Ferreola nigra* Radoszkowski 1888 is preoccupied by *Ferreola nigra* Marquet 1879 (= *Homonotus sanguinolentus* Fabricius), the replacement name *batrachiorum* of Dalla Torre, little known and never used before, is nevertheless valid and replaces automatically the *anomala* Haupt 1962 preoccupied by Priesner 1955.

Diagnosis: The female is characterised by its small size (smaller than 15 mm) and its typical color pattern which distinguishes the species from neighbouring species, depending on geographical area. The abdomen is always black which distinguish it from the abdominal red-colored *E. rhombica* and related forms in northern Africa. A similar species is *E. cyrenaica* which has a relatively long flagellomere I (4x as long as apical width, 1,5x as long as flagellomere II) and a typical color pattern (head and thorax touched with red except propodeum) whereas *E. manticata* has a shorter flagellomere I (maximum length: 3,8x as apicalwidth, 1,3x as long as flagellomere II) and a different pattern (completely black, forma *batrachiorum*, or with head and thorax including propodeum touched by red: form *tournieri*). The vertex behind the eyes is larger in *E. manticata* as in *E. cyrenaica*.

The male is characterised by its pale and translucent wings and silvery body setae. It has smooth sternites, which separates it from the *E. croceicornis*-species group with impressions on the sternites.

Discussion: The females of *manticata* show a remarkable geographical and individual variation in color. But we could not find any constant morphological character which justified splitting it into subspecies or different species, although each form has its distinct regional distribution. Therefore, we treat all color forms as forms of *E. manticata*. Color characters alone do not justify treating them as different species because color changes (from black to red) are a common, but not totally understood phenomenon in Pompilidae, probably depending on climate and temperature. The forms from southern Europe have reduced extent of red color on the abdomen in comparison to the central European forms. The f. *batrachiorum*, described from Israel, but also occurring in Corsica, is the most extreme black colored form. The most reddish colored f. *tournieri* Tournier however is described from north west Africa and is an exception to this rule.

Males are not distinguishable. They show a slight individual variation which do not covary with female color patterns. Males from the eastern Mediterranean often have pale spots on the pronotum.

Female: Length (7-) 11-12 (-14) mm. Black with variable red marks at head and thorax. Temples short, half as long as flagellomere X. Flagellomere I 3-3,8x as long as apical width, 1,3x as long as flagellomere II. Wings evenly darkened.

Variation: Females have been described as various subspecies or species, based after the pattern of red color on body. We treat all these taxa as forms of *manticata*. The following distinct forms are noteworthy:

***E. manticata* f. *manticata* Pallas:** Vertex and upper outer margin of eyes with narrow red band. Pronotum and propodeum red, apical point of scutellum and metanotum touched with red. Pronotal lobes and apical margin or half of pronotum and head might be black (transition characters to *manticata* f. *lichtensteinii*). The f. *manticata* occurs from Central Europe to Greece and Central Asia. It is a form of temperate climate areas.

***E. manticata* f. *lichtensteinii* Tournier:** (= *lichtensteinianus* Dalla Torre, 1897 see above): Black, propodeum red. This form occurs in south-west Europe, southern Italy, Turkey and Azerbeidshan. It replaces f. *manticata* in mediterranean climate areas in Europe and Turkey.

***E. manticata* f. *batrachiorum* (Dalla Torre)** [= *nigra* (Radoszkowski 1877); *iberitanica* (Wolf, 1970), *algojola* (Wolf, 1979); *anomala* (Haupt, 1962)]. It is a completely black form, which occurs in Corsica, Sardegna, northAfrica, the eastern mediterranean area and Central Asia. The *E. anomala* described from Israel and Egypt has also a short flagellomere I and long vertex. It belongs to *E. manticata* and is a **new synonym** of the latter.

Wahis, R. & C. Schmid-Egger (2002): The genus *Eoferreola* Arnold, 1935 in the Palaearctis with description of a new species (Hymenoptera: Pompilidae). Notes faunistiques de Gembloux 46: 39-73.

E. manticata f. tournieri Tournier (=*pici* sensu auct. nec Tournier): Vertex, face above scapus and outer margin of eyes red, frons sometimes darkened. Collar, pronotum, mesonotum, scutellum and propodeum completely red. Metanotum and metapostnotum with central red spot. Underside of basal flagellomeres reddish. One specimen has a dark margin at base of mesonotum. The *f. tournieri* occurs in northwest Africa from Tunisia to Morocco. A single and doubtful record comes from Sicily.

Male: Length 8-11 mm. Black, tergite II in most specimens with dark red band in basal two thirds. Erect setae and pubescence on head and propodeum silvery. Wings uniformly pale translucent.

Variation: Some specimens of Israel, described as *E. manticata f. claripennis* Priesner, have a whitish yellow band on apical margin of pronotum and such marks on tegulae and pronotal lobes. These specimens have also reddish marks on underside of flagellomeres. Most specimens of the south east mediterranean area belong to the form *claripennis*, but also some single specimens from other origins show this typical character. We treat *claripennis* only as a color of form *E. manticata*. *E. claripennis* is a new synonym.

Specimens from Kazakhstan sometimes have tergite II completely black. Also, the extent and color of pubescence on thorax show some variability from silvery whitish to brown in specimens in the eastern mediterranean and central asian area.

Geographic distribution: Mediterranean area to central Asia, northern to southern Switzerland and Hungary.

***Eoferreola mixta* (Tournier, 1895)**

Ferreola mixta Tournier, 1895: xii § Algeria: Oran (lectotype §; Genève) examined and designated .

Pompilus pharmaceuta Dalla Torre,1897: 310 (catalogue; replacement name for *Ferreola mixta*

Tournier,1895 nec *Sphex mixtus* Fabricius, 1798; *Pompilus mixtus* Radoszkowski, 1881, in *Pompilus*). *Sphex mixtus* Fabricius is a *Poecilopompilus* and *Pompilus mixtus* Radoszkowski (from Angola) belongs probably to *Hemipepsis* (material was destroyed). There is no reason to use the replacement name *pharmaceuta* Dalla Torre.

Paraferreola manticata forma mixta (Tournier); Haupt, 1927: 272-273 (key) £§ fig.139)

Paraferreola dentifer Haupt, in Nadig & Nadig 1935: 12 £§ Morocco: Casablanca (nomen nudum)

Tea mixta (Tournier); Wolf, 1970: 11 £ Morocco: Ixmoart.

Paraferreola manticata forma moroccana Haupt (in coll.) £ Morocco (nomen ineditum)

Diagnosis and Discussion: The female of *E. mixta* is characterized by its color pattern. The apical part of the head, the pronotum and the propodeum are red, the remaining body is black. *E. manticata* is smaller (less than 15 mm) with the markedly red colored form *tournieri* occurring in north Africa; the latter also has a red mesonotum and scutellum. *E. cyrenaica* from north Africa has a black propodeum, the remaining thorax is tinged by red. *E. mixta* is morphologically similar to *E. rhombica*. It is possible that *mixta* is only a form or subspecies of *rhombica* or of *anatolica*. For the moment we will treat the taxon *mixta* from north Africa as a valid species, defined by color pattern and distribution. See also the discussion of *rhombica*.

The male of *mixta* is characterized by dark wings, large size (more than 13 mm) and flat sternites. The male of *E. manticata* has pale and translucent wings, the remaining species in north Africa have sternal depressions.

Female : Length 16-20 mm. Black. Red are: back edge of head, spot at inner margin of eyes, flagellomeres, pronotum, propodeum, tarsi. Red color on head and tarsi might be reduced. Morphology similar to *rhombica* and *anatolica*. Wings clouded with narrow darker apical zone. In one specimen tergite II shows a very indistinct reddish lateral zone.

Male : Length 13-17 mm. Black, tergite II with red band (in basal two thirds). Setae on head and mesonotum pale brown, on propodeum black with brownish gleam (as in *anatolica*). Wings as in female.

Geographic distribution: Algeria, Morocco, Tunisia.

***Eoferreola neftae* Schmid-Egger new species**

Diagnosis and discussion: The male of *E. neftae* is characterized by its sternal emarginations, reddish flagellomeres, darkened wings, black pronotum and tibia III. Sternal depressions IV have bounding triangular projections, the space in between is rectangular and longer than wide. The similar *E. cyrenaica* has whitish-yellow spots on the pronotum and the tibia III, the space between the lateral edges on sternite IV is squarish or distally broader than basally. *E. syraensis* has black flagellomeres, the sternal emarginations IV are laterally rounded or with a bulge.

The sternal emarginations distinguish the species as a member of the *E. syraensis* group, together with *E. cyrenaica*. The form of the lateral projection of sternites suggests a close relationship between *E. neftae* and *E. cyrenaica*, whereas *E. syraensis* might be the sister species of both. But only a detailed character study can clarify the phylogenetic relationship between the *Eoferreola* species.

Male: Length 11-12,5 mm. Black, flagellomeres dark orange reddish. Flagellomere I darker than remaining flagellomeres. Inner margin of eye with small yellow spot. Mandibule with dark-reddish spot. Tergite II, tergite III and sternite II with large dark-reddish bands, band on tergite II extended to whole length of tergite, band on tergite II only in basal half of tergite. Face above clypeus with dense adjecting silvery pubescence and long erect setae on frons. Setae above ocelli as long as flagellomere X. Pronotum with coarse and short adjecting silvery pubescence and some long erect setae. Scutellum laterally, metanotum and propodeum above and apically-laterally covered with long and dense wool-like silvery pubescence.

Flagellomeres and face fig. xxx. Sternite III with small emargination in apical third, laterally with small bulge-like projections. Sternite IV with emargination on whole length (on visible part of sternite), laterally with large triangular edge-like projection. Projection as tall as ocellar diameter, nearly parallel, includes a long rectangular space. Sternite V with large, but indistinct emargination at surface, apical edge wide U-form emarginated. Apical edge of sternite VI deeply U-form emarginated. Sternite VII fig. xx. Wings brown darkened.

Wahis, R. & C. Schmid-Egger (2002): The genus *Eoferreola* Arnold, 1935 in the Palaearctis with description of a new species (Hymenoptera: Pompilidae). Notes faunistiques de Gembloux 46: 39-73.

Female: unknown.

Habitat: In Tunisia, the species was found in a small palm-oasis next to the Oasis Nefta north of Chott el Jerid. The males were caught by net-sweeping on flowering *Daucus carota*.

Etymology: The species is named after the type locality Oasis Nefta.

Geographic distribution: From Morocco to Egypt. All locations belong to the northern subsaharian border.

- Eoferreola rhombica* (Christ); Walter 1999: Live cycle of host *Eresus cinnaberinus*.

Diagnosis: The female of *E. rhombica* is characterized by its color pattern which is unique among the *Eoferreola* species considered here. Propodeum and band on tergite I and II are red (tergite I might be black in specimens from southeast Europe), the remaining thorax is black. The species varies in size. Specimens from central Europe measure between 11 and 15 mm, whereas specimens from Croatia, southern Italy and Greece can reach 22 mm maximum. We suspect that the smaller central European specimens belong to the same species as the larger specimens because we could not find any morphological differences. The size increases steadily from Germany and Austria to Greece; it is not possible to find a clear limit to separate two taxa. In addition, variation in the presence of the red band occurs across this geographic range.

The males have flat sternites (*distincta*, *neftae* and *cyrenaica* with sternal impressions), moderately darkened wings with a darker apical border (pale and translucent in *manticata*, completely darkened in

mixta and *anatolica*) and pale setae on the propodeum (darker setae in *anatolia* and silvery white setae in *erythraea*).

Discussion: The taxa *anatolica* and *erythraea* from southern Europe and palaearctic Asia and *mixta* from northwest Africa are morphologically identical to *rhombica*. Females differ in color pattern and in size, males in color of wings and color of propodeal setae. It is possible that all taxa belong to one widespread species which varies geographically in color. For the moment we treat all taxa as distinct species as defined below. Due to the variability of the color of propodeal setae, the distinction of the males in southeast Europe and Turkey remains a problem. XXX Perhaps size is an adaption to different sized prey spiders.

Female: Length 9-22 mm. Black with brownish pubescence. Propodeum red, tergite I and II with lateral red spots, often connected to a band. Spots on tergite I sometimes reduced or tergite I black. Base and apical margin of tergite I and apical margin of tergite II black. Temples as long as flagellomere II. Flagellomere I as long as OOL + 0,5 POL. Apical margin of mesosternum see fig. xx. Wings I and II slightly clouded with dark greyish apical zone outside of venation zone, in mediterranean species wing more or less regular dark.

Variation: The species varies considerable in size. Specimens from central Europe measures 9-15 mm, these from the Balkans 15-22 mm. A specimen from southern Italy (Gargano) is also 20 mm, whereas some specimens from Sicily are only 13-14 mm. The red color on tergite I is reduced in large specimens from Greece (tergite I with two small red spots) and southern Italy (tergite I black).

Male: Length 10-13 mm. Black, basal 2/3 of tergite II red. Sternite VIII in smaller species narrower with keel on basal half, in larger specimens broader with indistinct keel. Erect setae of head light brown (sometimes darker), of propodeum greyish white or pale brownish white. Wings I and II pale greyish transparent, with clouded zone on apex and apical margin of wings.

Variation: The males are very homogenous. Colour of setae varies from pale to darker brown, but it is always paler as in *syraensis* or *anatolica*.

Geographic Distribution: Central and southern Europe, north to 52,5° N latitude (Berlin).
